SECTION II: UNDERSTANDING CHILDHOOD TRAUMA

CHAPTER I. TRAUMA IN EARLY CHILDHOOD

IN THIS CHAPTER

- Childhood Trauma & Traumatic Stress Defined
- There are many types of traumatic experiences.
- Each child responds differently to traumatic events.
- Trauma can have lifelong effects.
- Early intervention and promoting resiliency can mitigate the effects of childhood traumatic stress.

What Is Childhood Trauma?
Throughout childhood, many (if not most) children experience some type of traumatic experience, an event that threatens or harms their emotional or physical well-being. The NCTSN estimates that one in four children will experience a traumatic event before they are 16 years old. Traumatic experiences can be the result of a natural disaster such as an earthquake or tornado. Children can also experience trauma within their communities as a result of community violence and racial, cultural, or socio-economic discrimination. Sexual and physical abuse, loss of a family member, bullying, or medical procedures can also be traumatic.

What Is Child Traumatic Stress?
While many children experience one or more traumatic event, every child has different physiological and psychological responses. Though most of us would agree that certain stresses are serious – experiencing a life-threatening attack or losing a loved one – we always have to remember that stress and trauma can only
be judged by those experiencing them. Variations in experiences, expectations, resources, and to some extent the way our brains and bodies are hard wired determine to a great extent what each individual perceives as stressful or traumatic.

Stress comes in many forms. It can be positive, alerting us to dangers. Some stresses can focus our attention on challenges that, if we can face them, will lead us to better places in our lives. Some stresses are tolerable but others can lead to long lasting physical and emotional affects. Stress and trauma can change the way we look at the world – making us more attentive to risk than to possibility. Furthermore, it does not take a major disaster to create levels of stress that impact health: the “hassles” and worries that come from feeling economically vulnerable or scrutinized because of one’s race, religion, gender, or sexuality, are potentially as or more dangerous than exposures to even serious one-time trauma.

**Child traumatic stress** is caused when a child is exposed to trauma or chronic stress and develops persistent reactions that affect the way they function on a day-to-day basis. Traumatic stress can make it difficult for a child to succeed at school or interact with others. It can also plant the seeds of physical and mental health problems that children may have to face for decades. Child traumatic stress can have an impact on many areas of development: emotional and behavior regulation; relationship formation and trust; maintaining attention while trying to learn new skills and knowledge. Children who have experienced traumatic stress may come to providers’ attention because of problems with their behavior, difficulties with sleeping or eating, or problems adapting to child care and school settings. In some cases, but certainly not all, childhood traumatic stress can lead to symptoms that are clinically diagnosed as post-traumatic stress disorder (PTSD). For example, the fifth edition of the Diagnostic and Statistical Manual (DSM-5) defined a developmental subtype of PTSD for children ages six years and younger. The preschool age-specific definition of PTSD is developmentally sensitive and focuses on recurrent psychological distress, avoidance behaviors, and increased arousal.

**Exposure and Experience of Trauma**

Exposures to chronic stress are fundamentally different than our experiences of chronic stress and should be assessed and addressed separately. *Exposure*
encompasses any population subjected to a traumatic event. Experience of trauma refers to how an individual responds to trauma exposure. Stress can be experienced as positive, tolerable, or chronically unsoothed (“toxic”) depending on:
- The event
- Characteristics of the individual (e.g. resiliency and vulnerability)
- Factors in the family and community

Some of those who experience stress will continue to show effects. Effects can be targeted with simple interventions, specialty services for physical and/or psychological complications, or coordinated teamwork (see Figure 1)

**Figure 1: Trauma Exposure, Experience, and Effects**

**Child Traumatic Stress and Gene Regulation**

Though it has long been recognized that early childhood adversity can cause lifetime problems, it is only more recently that we have come to isolate and understand some of the mechanisms involved. For example, the field of epigenetics has produced evidence that our experiences can alter the function of our genes. Though the links are not well understood, we now known that experiences can change the ways that genes regulate key processes within our bodies.

**Oxytocin**
A hormone that plays a role in how we relate to other people (e.g., emotions we feel when we see our children and the desire we have to be close to and nurture others).
Two systems that have been explored in relationship to stress and trauma are the genes that regulate oxytocin and glucocorticoid receptors.

Stress and trauma can alter both of these systems, leading an individual to being chronically “on-guard” around others. For example, children raised in stressful environments may be more likely to have elevated blood pressure or allergies as adolescents compared to children raised in less stressful environments. Epigenetics has also started to explain how parental exposure to stress and trauma, even before children are conceived, may be passed down to future generations.
Promoting Resiliency Through Early Intervention

The fact that people react differently to stress and trauma suggests that there might be ways to help those who experience traumatic events to feel less impact or recover more quickly. Resilience refers to the ability to buffer the impact of stress as it happens and recover from the impact more quickly and completely. Resiliency has two main components that are closely related: a person’s own abilities – both innate and learned – to regulate their emotions and behaviors at a time of challenge, and the resources – social and material – that a person can mobilize for protection and response.

There are many ways to define and measure recovery from a traumatic experience. For example, recovery can be measured by how quickly the body’s stress responses return to a normal state. Alternately, we might consider what it takes for someone to return to a state of optimism and security or adapt to new realities peacefully (for strategies on promoting resilience see Section III, Element VI: Addressing Trauma-Related Health and Mental Health).

Research in a number of fields support promising interventions for trauma and stress-related concerns in early childhood, some of which might be able to alter physiologic responses with long-term somatic and cognitive effects. Table 1 lists some of those with the strongest evidence:

---

**Resiliency**

The ability to:
- Blunt the impact of trauma as it happens and,
- Recover from the impact more quickly and more completely.

<th>Specific Benefits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Family Foundations</td>
<td>0-2</td>
<td>A universal prevention program to improve mother, child, and birth outcomes through promoting co-parenting quality among couples who are expecting their first child.</td>
<td>Improves mother-child relationship, reduces child behavior problems, supports parents in early childhood development.</td>
</tr>
<tr>
<td>Nurse-Family Partnership</td>
<td>0-2</td>
<td>A community-based program that provides comprehensive medical, nutritional, and social services to families with children aged 0-2</td>
<td>Improves family functioning, reduces child behavior problems, supports early childhood development.</td>
</tr>
<tr>
<td>Parent-Child Interaction Therapy</td>
<td>(3-11)</td>
<td>A group-based program that strengthens parenting competencies to promote young children’s social, emotional, and academic competence and prevent the development of conduct problems.</td>
<td>Enhances parent-child relationship, reduces child behavior problems, supports early childhood development.</td>
